Laryngealization or Pitch Accent – the Case of Danish Stød

Abstract
Recent proposals make Danish stød the phonetic manifestation of a HL tonal pattern compressed within one syllable. This review of the relevant aspects of Danish stød and intonation demonstrates that (1) such a tonal representation of stød is contradicted by the phonetic reality. (2) Stød is distributed in words according to the same principles across regional varieties of Danish, but tonal patterns are highly variable. (3) Pitch accents are aligned with stressed syllables, whereas stød occurs also in less than fully stressed syllables, devoid of autonomous pitch movements. (4) A word may have only one pitch accent, but Danish words may have more than one stød.

Index Terms: stød, laryngealization, tone, Danish

1. Introduction

The acoustic, perceptual as well as formal properties of standard Danish stød and standard and regional Danish intonation are documented in [1-10]. There is a long tradition in Denmark to describe stød as a kind of creaky voice, explicitly independent of tone, from Høysgaard [11-13] through Martinet [14], Hjelmslev and Andersen [15-16], to Basbøll [17-18]. The phonology and morphology are extensively accounted for and formalized in Basbøll’s Non-Stød Model [19-20]. Recent years, however, have seen proposals for a different analysis of Danish stød in [21-27], namely as the phonetic by-product of a H and L tone compressed within one syllable, inspired by Kiparsky’s analysis of Livonian stød, [28], although Kiparsky himself confines the tonal analysis to Livonian and does not extend it to Danish. There could be several incentives for such a proposal. (1) It is entirely justifiable on physiological grounds, given what is known about the larynx and the vocal folds in F0 lowering [29-31]. (2) In several South East Asian tone languages, low tone is often accompanied by laryngealization, as in Mandarin and Cantonese [32]. (3) There is an undisputed diachronic relation between the stød/non-stød distinction and the Accent I/Accent II distinction in Swedish and Norwegian, and the idea that stød arises from tonal contours is common in diachronic theories of stødgenesis [33-34]. (4) There is also a certain synchronic similarity in the distribution of Accent I/II and stød/non-stød. (5) Stød as pitch accent would unify Danish stød and the Scandinavian word accents in the current auto-segmental-metrical framework as, e.g., in [35].

2. Laryngealization

Stød is prototypically a kind of creaky voice: non-modal voice with aperiodic vibrations and irregular amplitude, often but not invariably accompanied by a local fundamental frequency perturbation, an abrupt and brief F0 dip, typically contained within the second half of long vowels or in the sonorant consonant after short vowels [1-2, 36], consonant with Basbøll’s contention in [19] that stød is a property of the second mora of binomoraic syllables. A series of acoustic and perceptual investigations in the early 2000s, summarized in [3-4], showed, however, that the exact acoustic properties, the timing, and the segmental domain of stød are highly variable: vocal fold vibrations are more or less explicitly irregular; the irregularity may onset simultaneously with the stressed vowel or later in the syllable nucleus; it may be contained within the syllable rhyme or it may spill over into a succeeding post-tonic syllable. The considerable acoustic variability does not seem to affect perception: Stød is as clearly audible in the word in the middle as on the left in Figure 1. A further notable characteristic is its robustness: In fast or non-distinct speech styles, where segments and syllables are freely weakened or lost, stød is faithfully produced and perceived. For a speculative account of the neuro-physiological mechanism behind this rather astounding acoustic variability in stød manifestation, see, e.g., [4]. – The variability in Danish stød is similar to what Blankenship reports in [37] about Mazatec and Mpi, and she finds laryngealization, i.e. stiffening of the vocal folds, which may or may not result in creaky voice, to be a better concept. So do Garellek and Keating in [38]. As in Danish stød, Gerfen and Baker find in [39] that laryngealization in Coatzospan Mixtec is highly variable within and across speakers and often realized with very subtle F0 and amplitude cues.

3. Pitch

Figures 1-6 and 8 are Praat screen dumps ([40]) with microphone signal above, spectrogram below and a superposed linearly scaled F0 contour. Words depicted in apparent isolation in Figures 1, 4, 5 are spliced out from within longer utterance contexts. These utterances were scripted and read aloud, except in Figure 8 which presents non-scripted speech.

3.1 Standard Danish in Copenhagen is not HL

Figure 1 demonstrates that (1) the F0 perturbation, the deep and steep fall, in the word on the left is contained within a very narrow time frame, not to be mistaken for a falling tone distributed over the whole syllable; and (2) there is an evident overall similarity, from lower stressed to higher unstressed syllable, in all three words. This is the F0 pattern associated with stressed and post-tonic syllables in Copenhagen Danish, cf. [8-10], apparent also in Figures 2 and 4-6. It would be characterized as L*H in current notational practice. A maximally developed F0 pattern describes a very modest initial F0 fall in the stressed vowel, succeeded by a steep and considerably larger rise, typically 3-4 semitones, to the first post-tonic syllable, and then a fall through succeeding post-tonics, if any. The shorter the stress group, the less extensive the F0 pattern: compare kanden in Figure 2, right, with the two long words in Figure 4. In the absence of any post-tonic syllable, all that remains is the slight initial fall as in grå and kat on the left in Figure 2. Note specifically the pairwise similarity between the F0 contours within the stressed vowels of (a) stødless kan(den) and grå, with its nearly invisible stød; (b) stødless kat and fyldt with stød and an explicit local F0 drop in the [l]; (c) stødless krudt(se)r and melk with stød and a likewise explicit local F0 drop in the [l]. The stressed vowels are also situated, pairwise, at the same level in the speaker’s F0 range. In other words, the presence or absence of post-tonic syllables does not affect the
scaling of the stressed syllables in the speaker’s F₀ range. That precludes a suggestion in [35:224-5] that the pitch pattern in Danish is in fact HL, only the H is delayed. But in the absence of any post-tonic syllable to carry the H, one would then expect the stressed syllable to move upwards in the range and take up its rightful H position. That does not happen.

Stød as a local F₀ perturbation, a brief and more or less explicit lowering of F₀, is independent of its location on the F₀ pattern. It may occur at the low turning point, prior to the rise to the post-tonic, as in læser in Figure 1 left, or fyldt med in Figure 2. It may occur at the top of the F₀ pattern as in koldt and vand in Figure 3, and low on the falling flank in a long series of post-tonics as in udendørserving in Figure 4. There is nothing to distinguish stød in one position from stød in any other position. The fundamental F₀ similarity between stød and non-stød is also evident in the three figures. Note particularly that there is nothing reminiscent of two HL pitch accents in the smoothly falling F₀ contour associated with the second and third parts of the compound udendørserving in Figure 4. In this respect it resembles the stødless word on the right, byggelegeplads.

Figure 3 depicts two stressed monosyllables succeeded by an unstressed word, vend det with and ven til without stød, and a stødless disyllable husse. Again, the overall patterns in the three disyllabic sequences are identical: a movement from lower stressed syllable to the higher post-tonic, three L*Hs.

Below the two arrows in Figure 6 are two very similar F₀ events: very steep and very local falls framing the sequence og vend. The first is associated with the glottal attack at the juncture before the vowel in og, the second accompanies the stød in vend. Presumably, no one would suggest that glottal attack at vowel onset be associated with a phonological pitch accent. Under a tonal analysis, then, the leftmost F₀ perturbation is the result of a glottal attack which is not quite a complete glottal closure here, but comes out as creaky voice,
Figure 5: ... vend det ... 'turn it' (left), ... ven til ... 'friend to' (mid), and ... bussen ... 'the bus' (right). Same speaker as in Figure 2.

Figure 6: Tag paletten og vend staffeliet 'Take the palette and turn the easel'. Same speaker as in Figure 2.

Figure 7: Prosodic stress group patterns in six varieties of Standard Danish. Vertical arrows point to the segmental anchor point. See further the text.

3.2 Regional varieties of standard Danish

Figure 7 depicts, in six different locations in Denmark, stylized tracings of the $F_0$ patterns associated with the prosodic stress group: a stressed syllable plus all succeeding unstressed syllables, if any, irrespective of intervening word boundaries. They are not impressionistic drawings or educated guesses but based on acoustic data from a considerable number of recordings of four speakers from each region, recording the same recorded material under identical conditions, cf. [8]. Heavy dots depict the location of short stressed vowels on the $F_0$ pattern, medium dots depict the extension in long stressed vowels, and fine dots depict the course of unstressed syllables in the prosodic stress group. In Bornholm, the horizontal arrows enclose movements which may be expanded or compressed in time, in concordance with the duration of the stressed vowel (long or short, the falling part), and the number of post-tonic syllables in the stress group (the rising part).

These $F_0$ patterns would adequately represent trisyllabic prosodic stress patterns. This is of no particular concern for Næstved, Aalborg, Tønder and Sønderborg, because $F_0$ will generally reach its low minimum already in the second post-tonic and continue low and level. But in Copenhagen, where the fall from the high turning point in the first post-tonic is less steep, it would typically continue to fall further, beyond what is depicted in Figure 7, only to level out around a fourth or fifth post-tonic, as in udendorservering in Figure 4. In other words, there is no fixed pitch relation between a L* and the termination of a preceding stress group pattern: the L* will be approached from above after short stress groups, cf. fyldt in Figure 2, and from below after long stress groups, cf. ... med rie ... in Figure 8, right.

The variation in shape and range of $F_0$ patterns is considerable. Differences among them are easier to capture when the governing principle in their execution is made explicit: In all of them, except Bornholm, there is one point only in the melodic fragment which is constrained in terms of its alignment with a segment in the prosodic stress group, as indicated by the arrows in the figure. This point is low relative to the first post-tonic in Copenhagen and Næstved and high in Aalborg, Tønder and Sønderborg. The former two may accordingly be characterized as L*H, the latter three as H*L.

whereas the same $F_0$ perturbation on the right would be an autonomous tonal gesture with a laryngealized side effect.

Note also how microprosodic effects may induce extensive $F_0$ movements in a vowel. An uninitiated observer might ascribe a falling pitch accent to the first syllable of bussen in Figure 5: the extent of its $F_0$ fall is nearly as comprehensive as the fall in vend. But the first steep part of the fall in bus- is due to the transition from the stop consonant to the vowel, the final steep movement is due to the transition from vowel to obstructed, and in fact the vowel is perceived as a non-dynamic level pitch. The pertinent, perceptible movement in the three disyllabic sequences – whether or not they contain a word boundary – is the movement from the lower stressed syllable to the higher post-tonic. None of these patterns contain a HL tonal sequence, they are all perceptually LH.

To sum up: The pitch pattern in Copenhagen Danish is essentially the same in words with and without stød, and it is LH, not HL. Furthermore, under temporal constraint the pattern is truncated rather than compressed into the stressed syllable. A representation in terms of a HL tone compressed into one syllable is as far removed from the phonetic reality as can be.
The anchor is invariably associated with the stressed vowel, namely with its offset across the board in the H*L varieties, but with its onset in Næstved. In Copenhagen the low turning point coincides with the offset of the stressed vowel if that vowel is short, and occurs about halfway through a long stressed vowel. Leaving out Bornholm for the moment, neither segments nor syllables in the prosodic stress group on either side of the anchor have separate tonal representations. They are simply strung out on the melody like pearls of varying length on an undulating string. Voiceless segments interrupt the melody and may have microprosodic effects but do not otherwise interfere with the score. A complete pattern only materializes in so far as there are syllables to carry it, otherwise it is truncated from the end. Accordingly, monosyllabic stress groups with a short vowel surrounded by voiceless consonants exhibit only the part of the melody indicated by the heavy dotted line part in the five patterns in Figure 7.

Figure 8: ...skal med rutebilen... ‘are going by bus’, male Aalborg speaker (left), female Næstved speaker (right).

Figure 8 shows two actual passages, ... skal med rutebilen... by a male speaker from Aalborg and a female speaker from Næstved. The frequency scale spans exactly an octave in both cases, so the ranges covered by the two patterns are immediately comparable. The offset of the stressed vowel (heavy dots) coincides exactly with the peak of the F₀ pattern in Aalborg, as stipulated in the stylization in Figure 7, and the fall from the peak is rapid and extensive. Since the vowel is short, it does not make it to the peak of the pattern in Næstved, and the peak therefore coincides with the first post-tonal syllable, as also stipulated in the stylization in Figure 7. The fall is not nearly as extensive as in Aalborg. The stød in the second part of the compound is rather weak in both instances, introducing a moderate perturbation only in Aalborg and hardly any at all in Næstved – although it is clearly audible in both cases.

Bornholm stands out from the other varieties by the very elastic relation between segments and F₀: the duration of the falling part of the tonal pattern varies – albeit slightly – with the duration of the stressed vowel so that the low turning point coincides with the offset of the vowel, be it short or long. The duration of the rise varies with the duration of the unstressed part of the stress group so that the rise terminates on the last post-tonic syllable. This latter variation is considerable, between one and many post-tonics, and perceptually the rise is more conspicuous than the fall. In other words, the pattern has three targets, a high onset, a low turning point and a high offset. There is, however, a limit to how fast the fall-rise may be executed, a compressibility maximum, and when this limit is reached, as in a monosyllabic stress group with a short vowel surrounded by voiceless consonants, the fall disappears, and what remains is a steep rise from a low onset to a high offset. Given that the fall may be deleted and that otherwise the rise in the F₀ pattern is perceptually more salient than the fall, Bornholm may also be adequately represented as L*H.

Among the L*H varieties, two have stød, Copenhagen and Næstved, whereas Bornholm does not. Likewise, among the H*L varieties Aalborg has stød, but Tender and Sonderborg do not. So much for an insoluble correlation between tonal movement and stød in Danish.

3.3 Stød under non-primary stress

Pitch accents in current phonological theory are associated with stressed syllables, and hence words – also composita – can each have one pitch accent only. But we have stød in syllables with non-primary stress, cf. udendorsservering in Figure 4 and rutebilen in Figure 8. And, contrary to expectations in a tonal representation, these syllables are not associated with independent, autonomous F₀ movements. And of course, when syllables with secondary stress can have stød, words will have more than one when the stressed syllable also has stød, as in, e.g., gol fbo ld ‘golf ball’, lan idsm an d ‘fellow countryman’.

4. Discussion and conclusions

Despite all the pros listed in the introduction, stød as the manifestation of a HL tone faces insurmountable empirical obstacles. There is nothing in the phonetic reality to support it. The overall F₀ pattern is similar in words with and without stød, and when stød is not accompanied by any F₀ perturbation at all, stød and non-stød F₀ patterns are identical. Likewise, the principles which govern the presence or absence of stød in words of different structure, are the same across regional varieties of Danish, in so far as they have stød at all, but F₀ patterns are not. In other words, the laryngealization typically present in Danish stød is not a phonetic accompaniment to a HL pitch accent. The causal relation is the opposite: the F₀ perturbation is by-product of laryngealization and not invariably present. Laryngealization is the articulatory, acoustic, and perceptual constant in stød production, F₀ perturbation is not. Such a state of affairs is not exclusive to Danish either. Voice quality differences in some of the South East Asian languages are not merely the synchronic phonetic accompaniment to tonal differences. On the contrary, tones developed from phonation types, not the other way around [41-43]. Furthermore, in so-called laryngeally complex languages, like Mpi [44], Jalapa Mazatec [38], and Comaltepec Chinantec [45], tonal and phonatory contrasts co-exist and cross-classify. Thus, laryngealization may accompany any tone, whether high or low.

Space does not permit a review of the similarly serious obstacles in the phonology and grammar of Danish stød, if represented as a H and L tone compressed in one syllable. The reader is referred to [6].

In conclusion: laryngealization as an autonomous syllable prosody, orthogonal to pitch and intonation, suffer none of the shortcomings attached to a tonal representation and is altogether more satisfactory than any representation of Danish stød as underlyingly tonal in nature.
